

Dynamics of the phyllosphere fungal microbiome
in Douglas-fir needles associated with
Nothophaeocryptopus gaeumannii in coastal
Oregon, USA

Foliar microbiomes

- Foliar microbiomes can be related to plant physiological traits such as stomatal conductance, also it is important for host resistance to diseases.
- *Nothophaeocryptopus gaeumannii* is an endophytic fungus that would mature and emerge in the spring while Douglas fir bud-breaking.

Figure 1. The phyllosphere and associated microbiotas, illustrating their roles (A) and the ecological and agronomic implications (B).

Research Questions

- Do foliar fungal communities relate to *Nothophaeocryptopus gaeumannii* occlusion therefore the SNC patterns? Can metabarcoding methods replace the traditional evaluation of SNC?
- Do the fungal communities and *Nothophaeocryptopus gaeumannii* differ among canopy locations due to macro- and micro- climates?

Elliott State Forest

Canopy depth was defined as the length from the tree-top to the lowest contiguous (vertical distance < 2m) branch

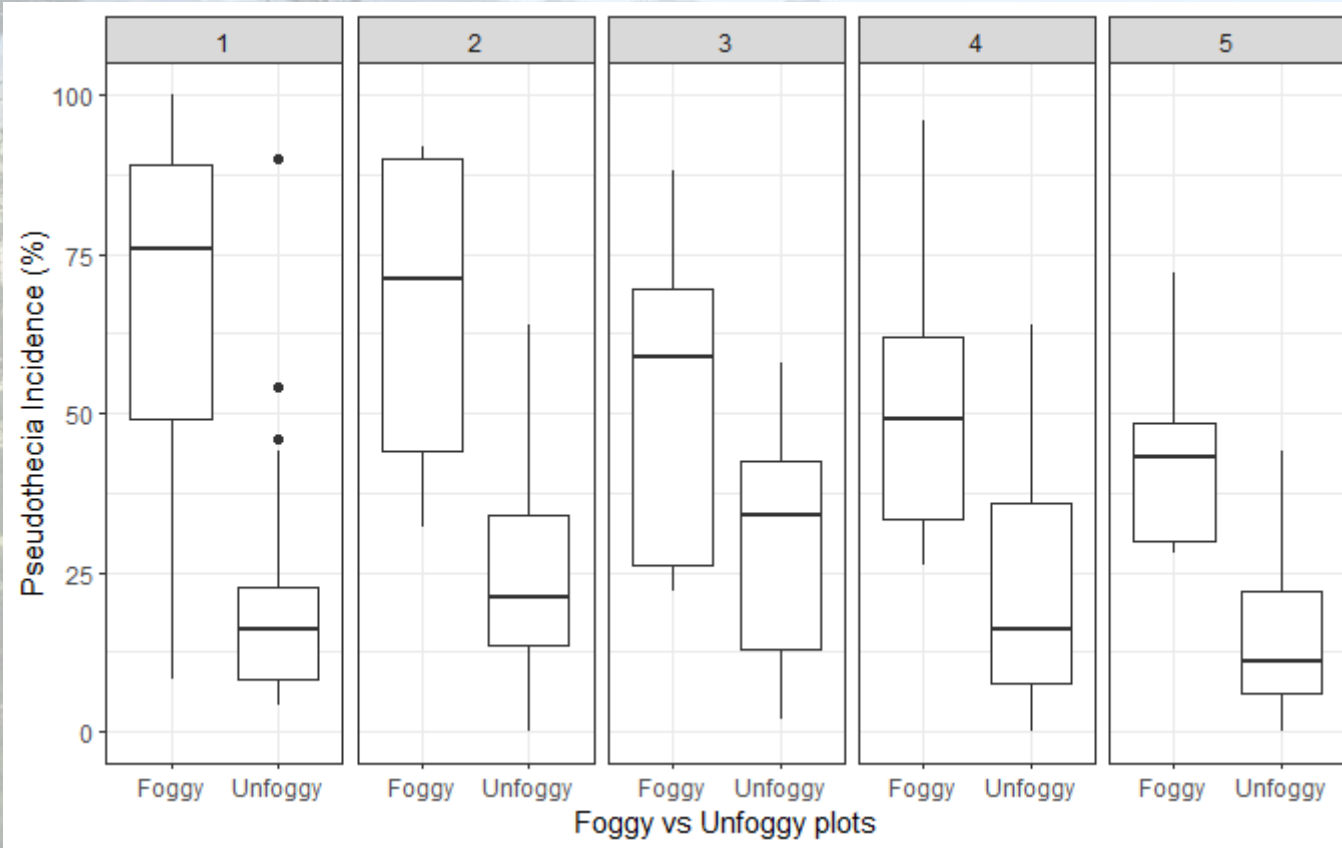

SNC samples: after evaluating the foliage retention, 50 needles were randomly selected from 3-year-old cohort, taped on an index card, and stored at -20°C before reading. (June 2023)

Microbiome samples: lyophilized for 24 hours for drying, then stored at -80°C before processing. (Nov 2022 & June 2023)

Preliminary results: SNC incidence

- SNC incidence in the foggy plots were 52% significantly more than non-foggy plots (GLMM, $p=0.02$).
- SNC incidence at the most bottom canopy (level 1) was 29% significantly higher than SNC incidence at the most top canopy (level 5) (GLMM, $p=0.007$).
- However, SNC incidence was not statistically different in 4 directions.

* Incidence = % of needles occluded by pseudothecia

Preliminary results: phyllosphere microbiomes

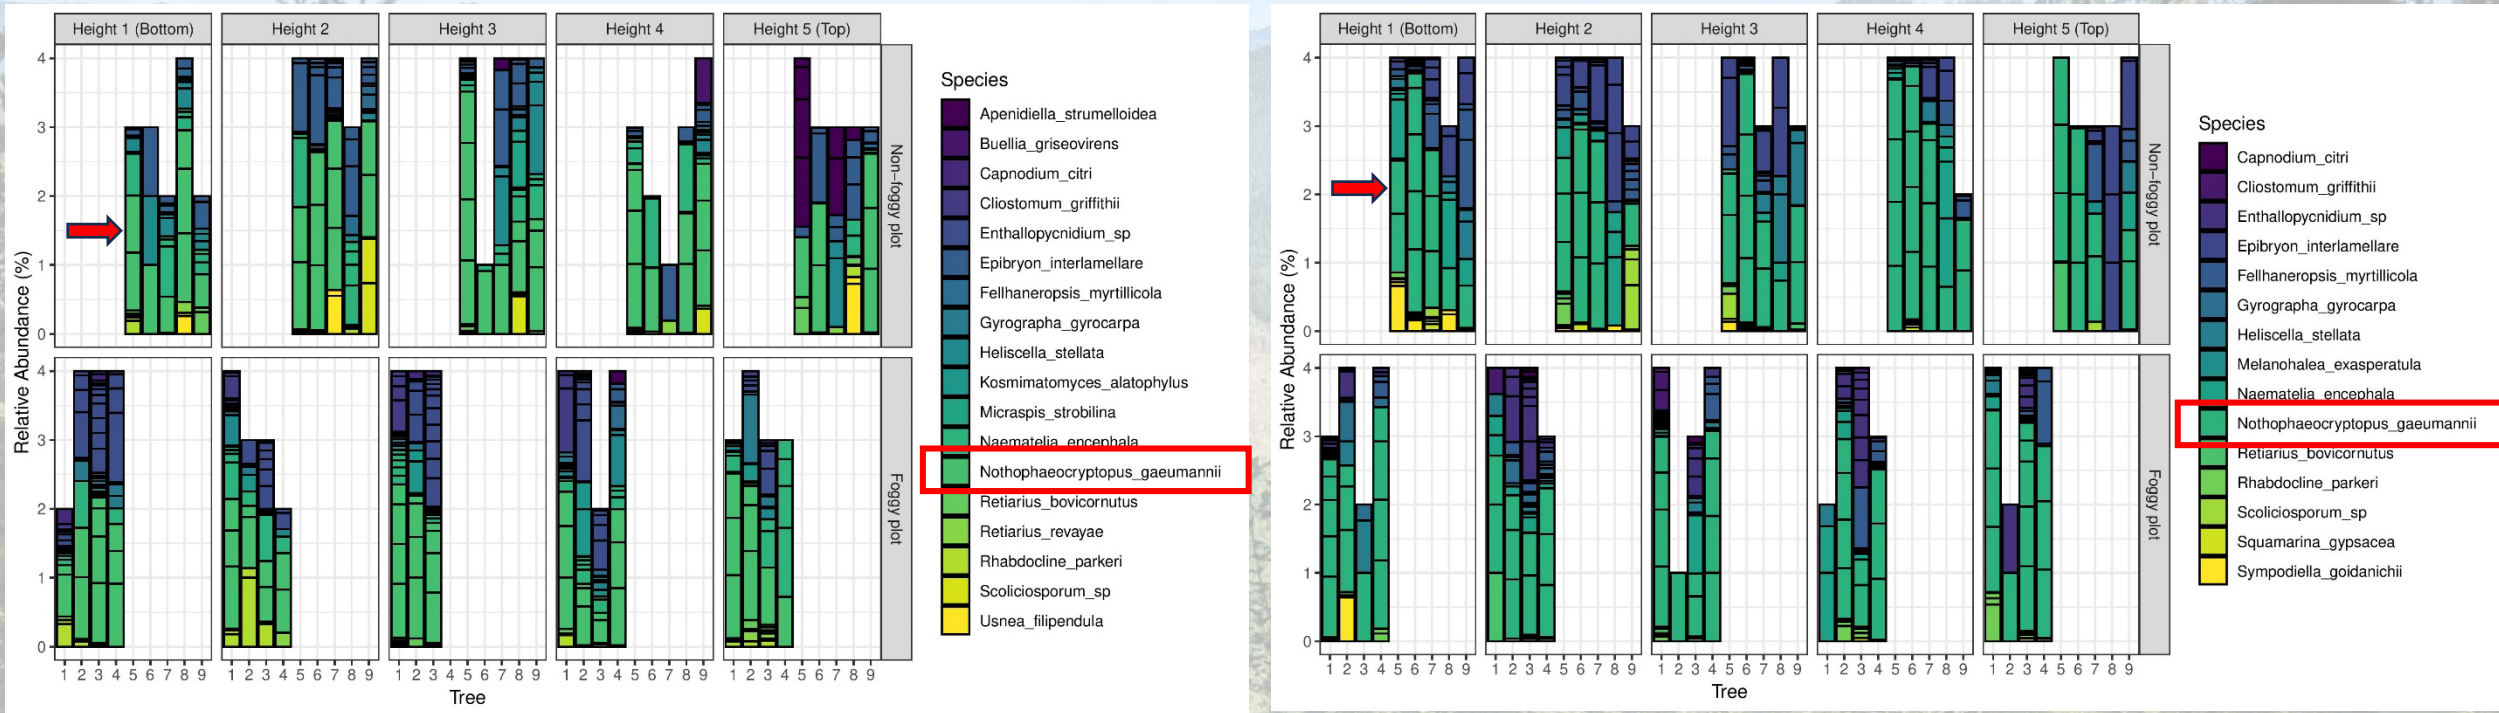

- The fungal phyllospheric communities were significantly different at foggy and non-foggy plots ($p=0.0001$), and among the different sampling heights ($p=0.002$).
- The fungal communities in the phyllosphere were different while they collected in 2022 and 2023 ($p=0.005$).
- However, the communities did not differ among sampling direction ($p=0.38$).

Preliminary results: phyllosphere microbiomes

Nov, 2022

June, 2023

- *N. gaeumannii* was abundant in most samples.
- Other needle pathogens, such as *Rhabdocline* spp.
- Lichen associated species, like *Cliostomum griffithii*, *Scoliciosporum* spp, and *Usnea* spp.
- From winter to spring: RA of *Nothophaeocryptopus gaeumannii* increasing.

Weather data

- Higher canopy has more dynamic changes on temperature.
- Fog site has higher dew point temperature than unfoggy site. => fog site has higher moisture and more fog/frost than unfoggy site.

Take home messages

For both *Nothophaeocryptopus gaeumannii* incidence and foliar fungal communities...

- Fog plays an important role.
- Vertical height is significant.
- The directions do not matter.

Incidence and Disease Severity Index

- 3-year-old needles used
- Incidence \rightarrow pseudothecial presence (%)
- Severity index \rightarrow Incidence * ratio of occluded stomates (%)

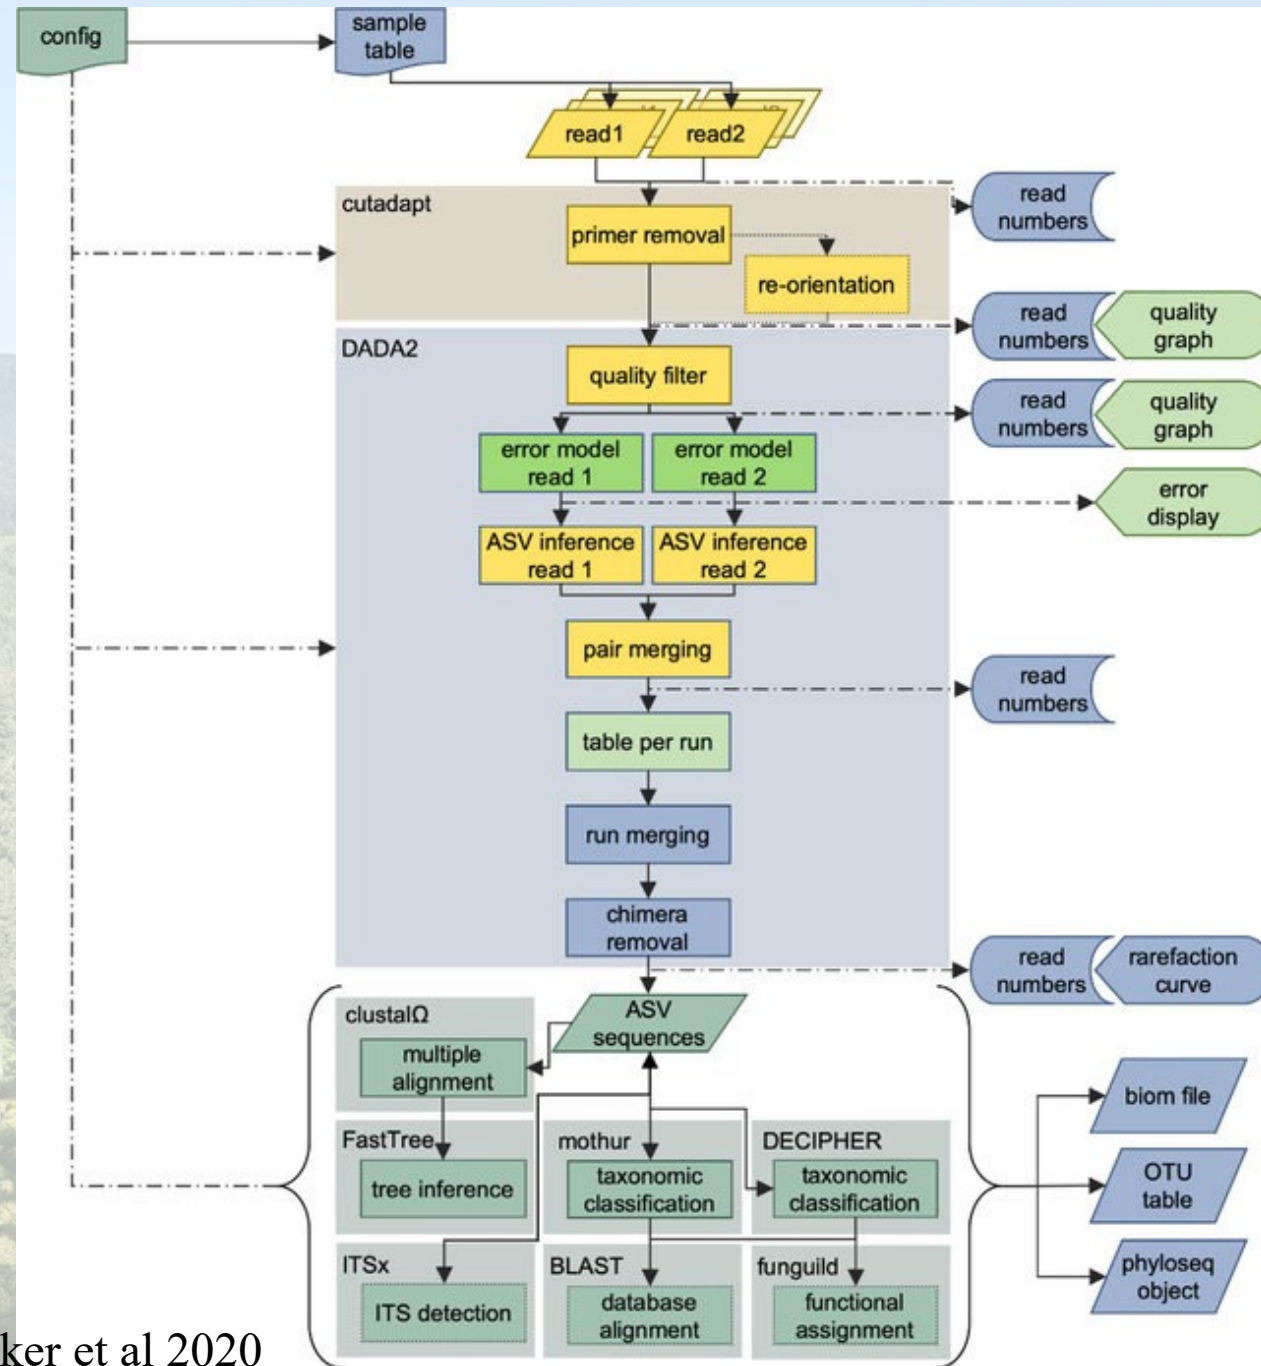

Microbiome analysis

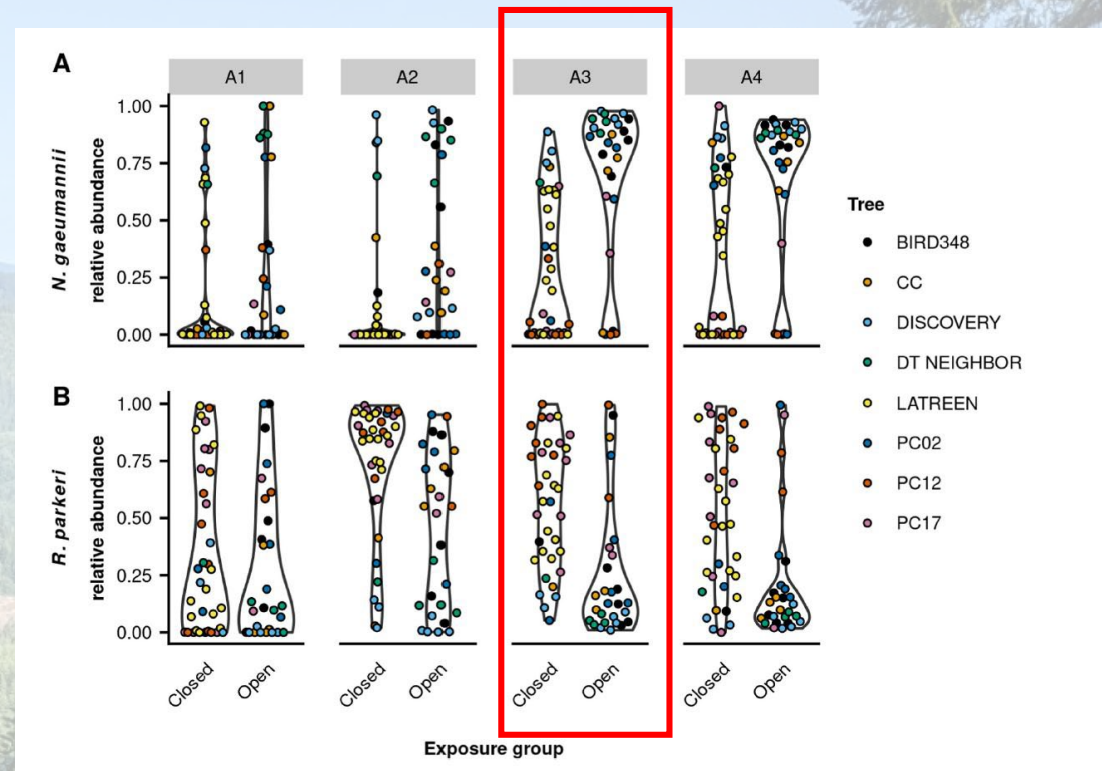

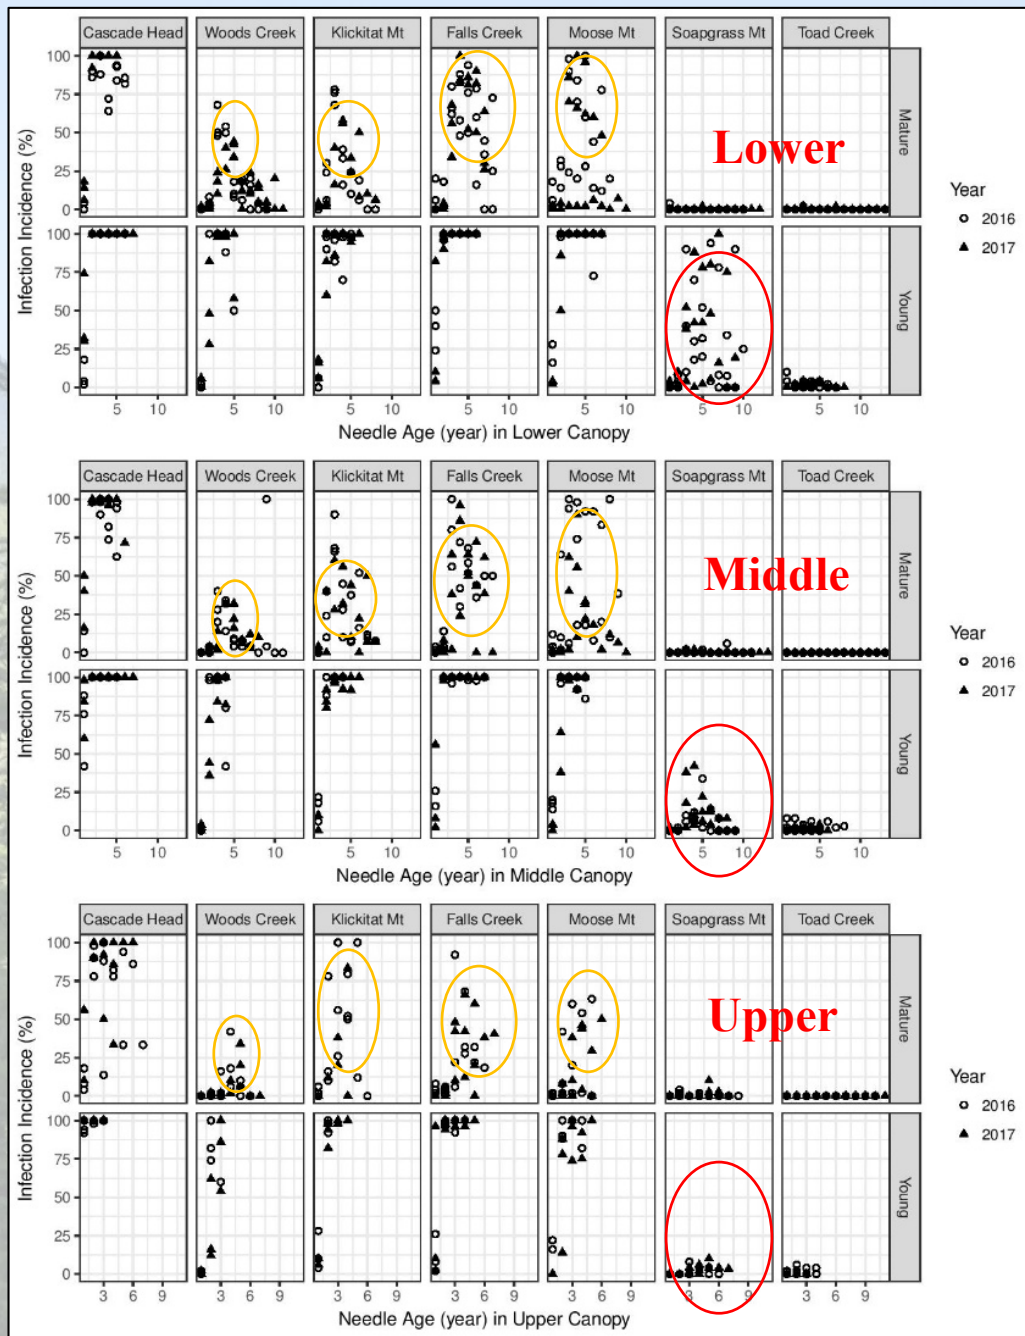

Two stage PCR applied. The ITS2 region was first amplified using the 5.85-Fun and ITS4-Fun primers, a 3-6 bp length heterogeneity spacer, and then followed by illumina adaptor sequences (Gervers et al 2022).

Conceptual workflow of Pipeline

Lan et al. 2019

Incidence = % of needles occluded by pseudothecia

Gervers et al. 2022
